

Designed by Julian Gutierrez, Presented by Nicolas Agostini

Session 11

Outline

- Improving Host to Device Memory Transfers
 - Pinned Memory
 - **Unified Memory**
- Concurrency
- Dynamic Parallelism

Improving Host to Device Memory Transfers

Memory Transfers

- We want to minimize the amount of time it takes to transfer data between host and device.
- Device to host memory bandwidth is much lower than device to device bandwidth

Memory Transfers

- We want to minimize the amount of time it takes to transfer data between host and device.
- How can we do this?
 - Reduce the amount of data we have to transfer! (if possible)
 - Achieve highest memory bandwidth between host and device. (Possible when using page-locked (or "pinned") memory, we are going to talk about it in this session)
 - Batching many small transfers into one larger transfer performs much better because it eliminates most of the per-transfer overhead
 - Data transfers between the host and device can sometimes be overlapped with kernel execution and other data transfers (we will talk about this in this session as well)

Memory Transfers

Remember

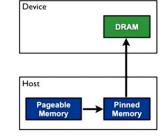

- When deciding whether to run on the GPU or on the CPU, we should consider the kernel execution time and the time it takes to copy data back and forth.
- We need to consider the cost of moving data across the PCI-e bus.

Pinned Memory (Page-Locked Data Transfers)

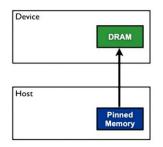

- Host (CPU) data allocations are pageable by default.
 - The GPU cannot access data directly from pageable host memory.
 - Due to this, the Cuda driver must:
 - Allocate a temporary page-locked block, or "pinned"
 - Copy host data to the pinned block
 - Transfer from pinned to device
 - Delete pinned block

Pageable Data Transfer

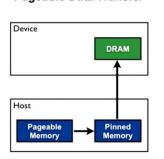

Pinned Data Transfer

Pinned Memory (Page-Locked Data Transfers)

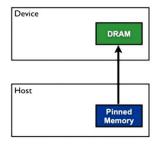

- cudaMallocHost()
 - Prevents OS from paging host memory
 - Allows PCI-e DMA to run at full speed
- cudaFreeHost()
- Allocations can fail so you need to check errors.

malloc

Pageable Data Transfer Pinned Data Transfer

cudaMallocHost

```
// allocate and initialize
h_aPageable = (float*)malloc(bytes); // host pageable
h_bPageable = (float*)malloc(bytes); // host pageable
checkCuda( cudaMallocHost((void**)&h_aPinned, bytes) ); //
host pinned
checkCuda( cudaMallocHost((void**)&h_bPinned, bytes) ); //
host pinned
checkCuda( cudaMalloc((void**)&d_a, bytes) ); // device
```

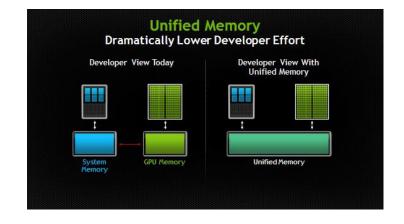

Pinned Memory (Page-Locked Data Transfers)

- You should not over-allocate pinned memory. Doing so can reduce overall system performance because it reduces the amount of physical memory available to the operating system and other programs.
- Transfers between the host and device are the slowest link of data movement involved in GPU computing, so you should take care to minimize transfers.

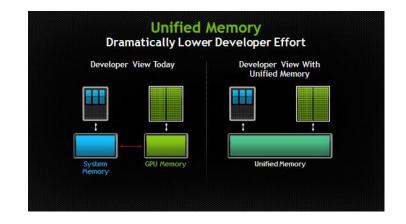

- In a typical PC or cluster node today, the memories of the CPU and GPU are physically distinct and separated by the PCI-Express bus.
- Data that is shared between the CPU and GPU must be allocated in both memories, and explicitly copied between them by the program.

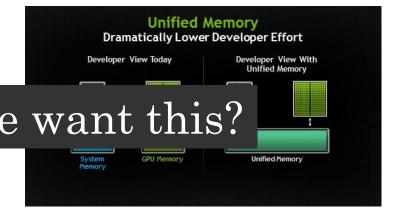

- Unified Memory creates a pool of managed memory that is shared between the CPU and GPU
- Managed memory is accessible to both the CPU and GPU using a single pointer
- The system
 automatically migrates data allocated
 in Unified Memory between host and device

- Unified Memory creates a pool of managed memory that is shared between the CPU and GPU
- both the CPU and G want this?
- The system
 automatically migrates data allocated
 in Unified Memory between host and
 device

- The driver handles the lookup and transfers
- Code: CPU and CUDA 6 with UM is basically the same.

```
CPU Code
                                         CUDA 6 Code with Unified Memory
void sortfile(FILE *fp, int N) {
                                           void sortfile(FILE *fp, int N) {
 char *data;
                                             char *data;
 data = (char *) malloc(N);
                                             cudaMallocManaged(&data, N);
 fread(data, 1, N, fp);
                                             fread(data, 1, N, fp);
 qsort(data, N, 1, compare);
                                             qs ort <<<...>>> (data ,N ,1,compare);
                                             cu daDeviceSynchronize();
 use_data(data);
                                             use_data(data);
 free(data);
                                             cudaFree(data);
```

- Notice the simplicity
 - One pointer used by the Host (CPU), and the GPU (kernels)

```
CPU Code
                                         CUDA 6 Code with Unified Memory
void sortfile(FILE *fp, int N) {
                                          void sortfile(FILE *fp, int N) {
 char *data;
                                            char *data;
                                            cudaMallocManaged(&data, N);
 data = (char *) malloc(N);
 fread(data, 1, N, fp);
                                            fread(data, 1, N, fp);
 qsort(data, N, 1, compare);
                                            qs ort <<<...>>> (data ,N ,1,compare);
                                            cudaDeviceSynchronize();
 use_data(data);
                                            use_data(data);
 free(data);
                                            cudaFree(data);
```

- Allows Performance through data locality
 - Data migration happens on demand between CPU and GPU.
- Despite this, tuned programs that don't use UM will perform better due to added complexity in the Driver.

```
CPU Code
                                         CUDA 6 Code with Unified Memory
void sortfile(FILE *fp, int N) {
                                           void sortfile(FILE *fp, int N) {
                                             char "data;
 data = (char *) malloc(N);
                                             cudaMallocManaged(&data, N);
 fread(data, 1, N, fp);
                                             fread(data, 1, N, fp);
 qsort(data, N, 1, compare);
                                             qs ort <<<...>>> (data ,N ,1,compare);
                                             cu daDeviceSynchronize();
 use_data(data);
                                             use_data(data);
 free(data);
                                             cudaFree(data);
```

- Cuda stream:
 - A stream in CUDA is a sequence of operations that execute on the device in the order in which they are issued by the host code.
 - Operations from different streams can be interleaved
 - Stream IDs are used as arguments to async calls and kernel launches

```
cudaStream_t stream1, stream2, stream3, stream4;
cudaStreamCreate (&stream1);

cudaMalloc (&dev1, size);

cudaMallocHost (&host1, size);

cudaMemcpyAsync (dev1, host1, size, H2D, stream1);
kernel2 <<< grid, block, 0, stream2 >>> (..., dev2, ...);
kernel3 <<< grid, block, 0, stream3 >>> (..., dev3, ...);
cudaMemcpyAsync (host4, dev4, size, D2H, stream4);
some_CPU_method ();

Fully asynchronous / concurrent

Data used by concurrent operations should be independent
```

Cuda stream:

A stream in CUDA is a sequence of operations that execute on the device in the order in which they cudaMemcpyAsync Operations fi Stream IDs a nches Asynchronous host-device memory copy returns control immediately to CPU • Requires pinned host memory (allocated ired on host with cudaMallocHost) Kerneiz <<< grid, block, u, streamz >>> (..., devz, ...) , potentially kernel3 <<< grid, block, 0, stream3 >>> (..., dev3, ...); overlapped cudaMemcpyAsync (host4, dev4, size, D2H, stream4); some CPU method (); Fully asynchronous / concurrent

Data used by concurrent operations should be independent

Synchronization

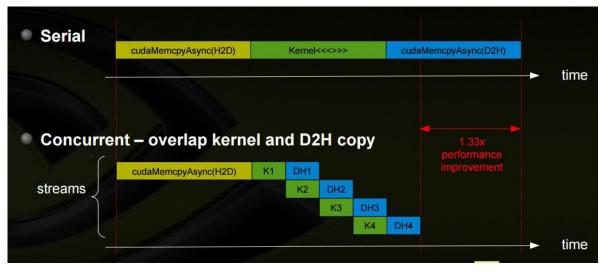

- cudaThreadSynchronize()
 - Blocks until all previously issued CUDA calls from a CPU thread are complete
- cudaStreamSynchronize (stream):
 - Blocks until all CUDA calls issued to given stream have completed.
- cudaStreamQuery (stream)
 - Indicates whether stream is idle.
 - Doesn't block CPU thread
- CudaStreamWaitEvent (event)
 - wait for event in a stream

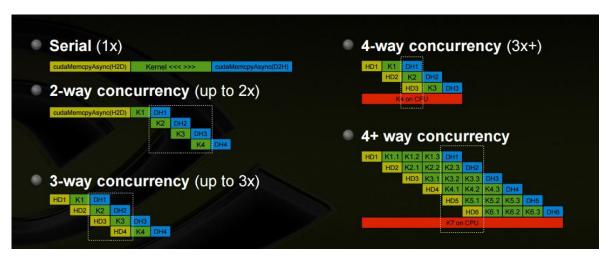

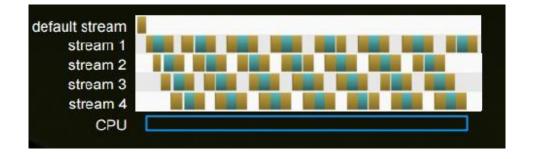

- Example results from a Tiled DGEMM
 - CPU
 - 43 Gflops
 - GPU
 - Serial: 126 Gflops (2.9x)
 - 2-way: 177 Gflops (4.1x)
 - 3-way: 262 Gflops (6.1x)
 - GPU + CPU
 - 4-way: 282 Gflops (6.6x)

- If we have multiple streams, how many different ways exist to do a complete kernel operation (H2D/Kernel/D2H)?
 - We need to take into account how many Copy Engines are available!
 - Lets look at 2 methods on how we could do these operations.

Method 1

```
for (int i = 0; i < nStreams; ++i) {
  int offset = i * streamSize;
  cudaMemcpyAsync(&d_a[offset], &a[offset], streamBytes, cudaMemcpyHostToDev
  kernel<<<streamSize/blockSize, blockSize, 0, stream[i]>>>(d_a, offset);
  cudaMemcpyAsync(&a[offset], &d_a[offset], streamBytes, cudaMemcpyDeviceToH
}
```

- Method 1
 - CHD1, K1, CDH1, CHD2, K2, CDH2, ...
- Queues:
 - Copy engine
 - CHD1, CDH1, CHD2, CDH2, ...
 - Kernel
 - K1, K2, ...

```
for (int i = 0; i < nStreams; ++i) {
  int offset = i * streamSize;
  cudaMemcpyAsync(&d_a[offset], &a[offset], streamBytes, cudaMemcpyHostToDev
  kernel<<<<streamSize/blockSize, blockSize, 0, stream[i]>>>(d_a, offset);
  cudaMemcpyAsync(&a[offset], &d_a[offset], streamBytes, cudaMemcpyDeviceToH
}
```

Method 2

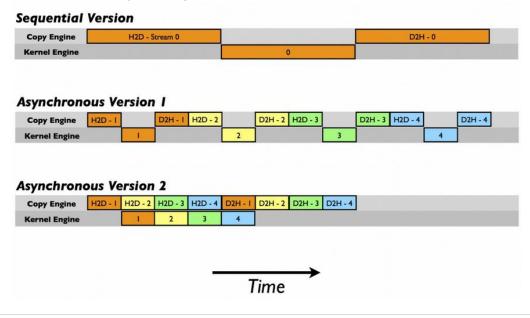

```
for (int i = 0; i < nStreams; ++i) {
 int offset = i * streamSize;
 cudaMemcpyAsync(&d a[offset], &a[offset],
                  streamBytes, cudaMemcpyHostToDevice, cudaMemcpyHostToDevic
for (int i = 0; i < nStreams; ++i) {
 int offset = i * streamSize;
 kernel<<<streamSize/blockSize, blockSize, 0, stream[i]>>>(d a, offset);
for (int i = 0; i < nStreams; ++i) {
 int offset = i * streamSize;
 cudaMemcpyAsync(&a[offset], &d a[offset],
                  streamBytes, cudaMemcpyDeviceToHost, cudaMemcpyDeviceToHos
```

- QUEUES:
 - COPY ENGINE
 - · CHD1 CDH1, CHD2
 - Kernel
 - K1, K2, ...

Added to the other Copy Engine

 Now that we've copied data efficiently and overlapped with execution. Another simple example:

```
int main()
    const int num streams = 8;
    cudaStream t streams[num streams];
    float *data[num streams];
    for (int i = 0; i < num streams; <math>i++) {
        cudaStreamCreate(&streams[i]);
        cudaMalloc(&data[i], N * sizeof(float));
        // launch one worker kernel per stream
        kernel <<<1, 64, 0, streams[i] >>> (data[i], N);
        // launch a dummy kernel on the default stream
        kernel <<<1, 1>>> (0, 0);
    cudaDeviceReset();
    return 0;
```

- When you execute asynchronous CUDA commands without specifying a stream:
 - runtime uses the default stream.
 - Before CUDA 7, the default stream is a special stream which implicitly synchronizes with all other streams on the device.
- CUDA 7 introduces a new option to use an independent default stream for every host thread, which avoids the serialization of the legacy default stream.
- --default-stream per-thread

--default-stream per-thread

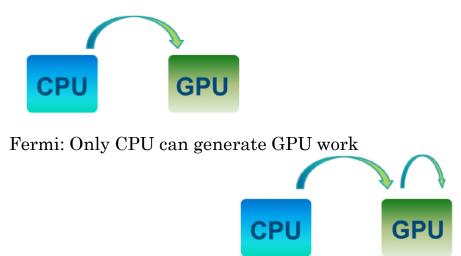

- Device-side kernel launches
 - Kepler GK110 architecture
 - Typical use cases
 - Dynamic load balancing
 - Data-dependent execution
 - Recursion
 - Library calls from kernels
 - Programmability and maintainability

Kepler: GPU can generate work for itself

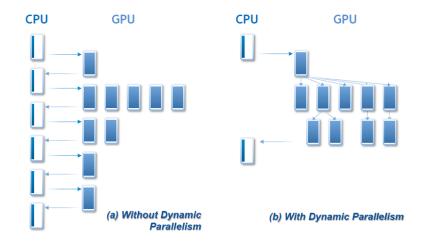

Fixed grid vs dynamic grid for a turbulence simulation mode

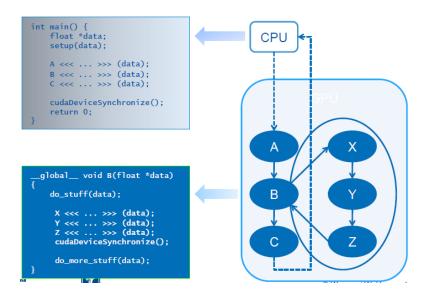

CPU-GPU without and with dynamic parallelism

Nested dependencies

Syntax

```
Kernel_name <<<Dg, Db, Ns, S>>> ([kernel arguments]);
```

- Dg is of type dim3 and specifies the dimensions and size of the grid
- Db is of type dim3 and specifies the dimensions and size of each thread block
- Ns is of type size_t and specifies the number of bytes of shared memory that
 is dynamically allocated per thread block for this call
- S is of type cudaStream_t and specifies the stream associated with this call

Example

LU decomposition (Fermi)

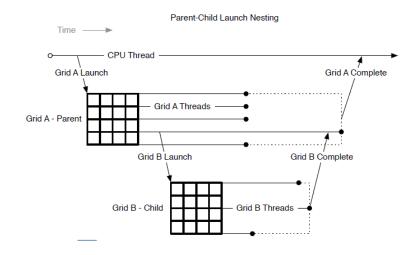

dgetrf(N, N) { for j=1 to N (step=64) for i=1 to 64 (step=1) idamax<<< >>> idamax(); memcpv dswap<<< >>> dswap(); memcpy dscal(); dscal<<<>>>> dger<<< >>> dger(); next i memcpy dlaswap(); dlaswap<<< >>> dtrsm<<<>>>> dtrsm(); dgemm<<<>>>> dgemm(); next i CPU code GPU code

LU decomposition (Kepler)

```
dgetrf(N, N) {
  daetrf<<<>>>>
                            dgetrf(N, N) {
                               for j=1 to N (step=64)
                                 for i=1 to 64 (step=1)
                                   idamax<<<>>>>
                                   dswap<<< >>>
                                   dscal<<<>>>>
                                   dger<<< >>>
                                 next i
                                 dlaswap<<< >>>
                                 dtrsm<<<>>>>
                                 dgemm<<<>>>>
                               next j
  synchronize();
  CPU code
                                 GPU code
```

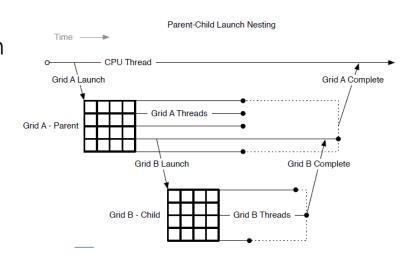

- Synchronization
 - Parent to child: memory consistency
 - Child to parent: after cudaDeviceSynchronize()

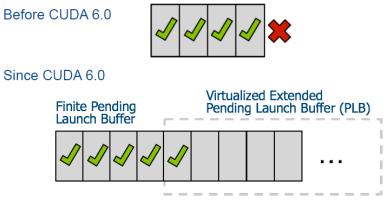

Memory Model

- Child sees parent state at time of launch
- Parent sees child writes after sync
- Constants are immutable
- Local and shared memory are private

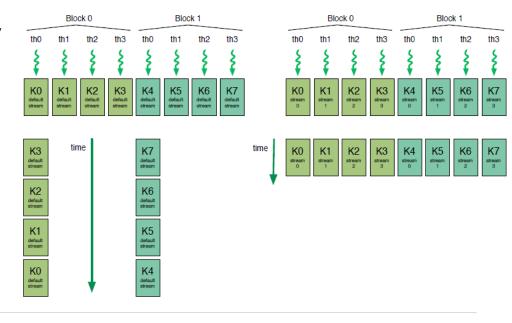

- Launch pool size
 - Fixed-size pool: default 2048
 - Variable-size pool

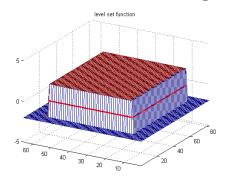

Streams

To guarantee concurrency

```

Another Recursive Example

- To understand recursive usage
 - Classic Fibonacci series: 0, 1, 1, 2, 3, 5...
 - **CPU Recursive**
 - GPU non recursive nonDP
 - GPU recursive DP

Fibonacci – CPU Recursion

```
int fib(int n){
   if (n == 0 || n == 1 ){
      return n;
   }
   else{
      return fib(n-1) + fib(n-2);
   }
}
```

Fibonacci – GPU Basic Kernel

```
__global___void fib_kernel_plain(int n, long int* vFib){
    int tid = threadIdx.x + blockDim.x * blockIdx.x;
    if (tid > n/32)
        return;

    if (n == 0 || n == 1){
        return;
    }
    for(int i=tid*32 + 2; i <= n && i < tid*32 + 32; i++){
        vFib[i] = vFib[i-1] + vFib[i-2];
    }
}</pre>
```

Fibonacci – GPU Recursion Kernel MARK

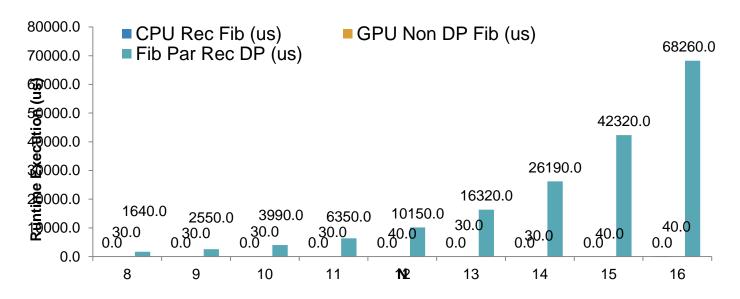

```
__global__ void fib_kernel_par_rec(int n, unsigned long int* vFib){
    if (n == 0 | | n == 1)
        return;

    fib_kernel_par_rec<<<1, 1>>>(n-2, vFib);
    fib_kernel_par_rec<<<1, 1>>>(n-1, vFib);
    cudaDeviceSynchronize();
    vFib[n] = vFib[n-1] + vFib[n-2];
}
```

What is and what is not dynamic parallelism **MLAN**

- CDP ensures better work balance, and offers advantages in terms of programmability
- However, launching grids with a very small number of threads could lead to severe underutilization of the GPU resources
- A general recommendation
 - Child grids with a large number of thread blocks.
 - Or at least thread blocks with hundreds of threads, if the number of blocks is small

- Nested parallelism for tree processing
 - Thick tree nodes (each node deploys many threads) work well
 - And/or when branch degree is large (each parent node has many children)
 - As the nesting depth is limited in hardware, only relatively shallow trees can be implemented efficiently.
